### COMPERATIVE CHEMISTRY OF CHROMIUM, MOLYBDENUM AND TUNGSTEN:

#### OXIDATION STATES:

The ground state of Chromium and Molybdenum are  $d^5s^1$ , with stable half- filled configuration, whilst Tungsten has a  $d^4s^2$  arrangement. From the electronic structure Cr and Mo have (+I) to (+VI) whereas W have (+II) to (+VI) oxidation states. Cr. (+II) is reducing, Cr(+III) is the most stable and important and Cr(+IV) is strongly oxidising. The stable states for Mo and W are (+VI) though Mo (+V) and W(+V) are stable in water. Cr(+VI) is strongly oxidising whereas Mo(+VI) and W (+VI) are stable. Similarly Cr(+III) are very stable but Mo(+III) and W(+III) are strongly reducing. This property is usual as we go down a group, the higher oxidation state become more stable and the lower oxidation states become less stable. The Compounds of all the three metals are given below:

(+II)	(+III)	(+IV)	(+V)	(+VI)
	$Cr_2O_3$	$CrO_2$		$CrO_3$
		$MoO_2$	$Mo_2O_5$	$MoO_3$
		$WO_2$		$WO_3$
$CrF_2$	$CrF_3$	$CrF_4$	$CrF_5$	
$CrCl_2$	$CrCl_3$	$CrCl_4$		
$CrBr_2$	$CrBr_3$	$CrBr_4$		
$CrI_2$	$CrI_3$	$CrI_4$		
	$MoF_3$	$MoF_4$	$MoF_5$	$MoF_6$

MoCl <sub>2</sub>	MoCl <sub>3</sub>	MoCl <sub>4</sub>	MoCl <sub>5</sub>	
MoI <sub>2</sub>	MoI <sub>3</sub>			
		WF <sub>4</sub>	WF <sub>5</sub>	WF <sub>6</sub>
WCl <sub>2</sub>	WCl <sub>3</sub>	WCl <sub>4</sub>	WCl <sub>5</sub>	WCl <sub>6</sub>
WBr <sub>2</sub>	WBr <sub>3</sub>	WBr <sub>4</sub>	WBr <sub>5</sub>	WBr <sub>6</sub>
WI <sub>2</sub>	WI <sub>3</sub>			

(+IV) State:

A limited number of Cr(+IV) compounds are known. These are very strong oxidising agents, they are (CrO<sub>4</sub>)<sup>-2</sup>, dichromate (Cr<sub>2</sub>O<sub>7</sub>), chromium trioxide (CrO<sub>3</sub>), oxohalides CrO<sub>3</sub>X<sup>-</sup>, CrO<sub>2</sub>X<sub>2</sub> (X = F, Cl, Br or I) CrOX<sub>4</sub> (X = F or Cl) and CrF<sub>6</sub>.

MoO<sub>3</sub> and WO<sub>3</sub> are formed. They are acidic and not attacked by acid except HF, but they are dissolved in NaOH forming MoO<sub>4</sub><sup>2-</sup>, and WO<sub>4</sub><sup>2-</sup> ions. The oxides of Mo and W differ with of chromium in several ways:

i) They have almost no oxidising properties.

ii) They are insoluble in water.

iii) Their melting point is much higher CrO<sub>3</sub> = 197°C, MoO<sub>3</sub> = 795°C and WO<sub>3</sub> = 1473°C.

iv) Their colour and structure are different.

(+V) State:

There are few Cr(+V) compounds are known, they are unstable and decompose to Cr(+III) and Cr(+VI) compounds. Examples are CrF<sub>5</sub>, K<sub>3</sub>CrO<sub>8</sub>

MoF<sub>5</sub> has a tetrameric structure of four octahedra joined into a ring. MO<sub>2</sub>Cl<sub>10</sub> is also known compound. Tungsten have WX<sub>5</sub> (X = F, Cl, Br) compounds.

(+IV) State:

Chromium (+IV) compounds are very rare.  $\text{CrF}_4$ ,  $\text{CrO}_2$ ,  $\text{CrOF}_2$  is known compound.  $\text{CrO}_2$  is black in colour and has some metallic conductivity. It is also ferromagnetic and is widely used to make high quality magnetic recording tapes.

$\text{MoO}_2$  and  $\text{WO}_2$  are well known compounds.

(+III) State:

(+III) Oxidation state of chromium is the most important and most stable compound of chromium. These compounds are very stable in an acidic solution but it is easily oxidised to (+VI) state in alkaline solution.  $\text{Cr}_2\text{O}_3$  is a green solid which is used as a pigment. All the anhydrous  $\text{CrX}_3$  halides are known.  $\text{Cr}^{3+}$  ions form an enormous number and variety of complexes.

$\text{Mo}^{3+}$  and  $\text{W}^{3+}$  do not exist as oxides, but all halides i. e  $\text{MoX}_3$  ( $\text{X} = \text{F}, \text{Cl}, \text{Br}$  or  $\text{I}$ ) are known except  $\text{WF}_3$ . These compounds do not contain simple ions.  $\text{Mo}^{+III}$  are fairly stable, but slowly oxidised in air and hydrolysed in water. They form octahedral complexes with halide ion in solution.

(+II) State:

$\text{Cr}^{+II}$  compounds are well known  $[\text{Cr}(\text{H}_2\text{O})_6]^{2+}$  ion is sky blue coloured and one of the strongest reducing agents known in aqueous solution.  $\text{Cr}^{+II}$  ion may stabilize by forming complex compounds.

$\text{CrX}_2$  ( $\text{X} = \text{F}, \text{Cl}, \text{Br}$  or  $\text{I}$ ) are well known compounds.  $\text{Mo}$  and  $\text{W}$  do not form difluorides but  $\text{MX}_2$  ( $\text{X} = \text{Cl}, \text{Br}$  and  $\text{I}$ ) are known. They are usually made by reduction or thermal decomposition of higher halides. They do not exist in simple ion but form cluster compounds.

(+I) States:

The oxidation state (+I) expected for the atoms with a  $d^5s^1$  configuration is very uncommon. Trisdipyridyl Chromium (I) perchlorate  $[\text{Cr}(\text{dipyridyl})_3]^+ \text{ClO}_4^-$  is known  $\text{Mo}$  and  $\text{W}$  form sandwich type structures.

Zero State, (-I) and (-II) state

The zero oxidation arises in metal carbonyl such as  $\text{M}(\text{CO})_6$ , where the  $\sigma$  – bonding electrons are donated by the CO group to the metal and strong  $d_{\pi}-p_{\pi}$  back bonding occurs from the filled metal orbitals.
